## Lecture 4: Nuclear Structure 2

- Independent vs collective models
- Collective Model
- Rotation
- Vibration
- Coupled excitations
- Nilsson model

## Nuclear Models

- No useful fundamental \& universal model exists for nuclei
- E.g. based on the nuclear interaction, how do we describe all nuclear properties?
- Promising approaches include "ab initio" methods, such as Greens Function Monte Carlo, No-core shell model, Coupled cluster model, density functional theories
- Generally one of two classes of models is used instead
- Independent particle models:
- A nucleon exists within a mean-field (maybe has a few interactions)
- E.g. Shell model, Fermi gas model
- Collective models:
- Groups of nucleons act together (maybe involves shell-model aspects)
- E.g. Liquid drop model, Collective model

## Collective Model

- There are compelling reasons to think that our nucleus isn't a rigid sphere
- The liquid drop model gives a pretty successful description of some nuclear properties. ...can't liquids slosh around?
- Many nuclei have non-zero electric quadrupole moments (charge distributions)
...this means there's a non-spherical shape.
...can't non-spherical things rotate?
- Then, we expect nuclei to be able to be excited rotationally \& vibrationally
- We should (and do) see the signature in the nuclear excited states
- The relative energetics of rotation vs vibration can be inferred from geometry
- The rotational frequency should go as $\omega_{r} \propto \frac{1}{R^{2}}$ (because $I \equiv \frac{L}{\omega}$ and $I \propto M R^{2}$ )
- The vibrational frequency should go as $\omega_{v} \propto \frac{1}{(\Delta R)^{2}}$ (because it's like an oscillator)

- So $\omega_{r} \ll \omega_{v}$
$\downarrow$

## Rainwater's case for deformation

- A non-spherical shape allows for rotation ...but why would a nucleus be non-spherical?
- Consider the energetics of a deformed liquid drop (1. Rainwater, Phys. Rev. (1950)
- $B E_{\text {SEMF }}(Z, A)=a_{v o l} A-a_{\text {surf }} A^{2 / 3}-a_{\text {coul }} \frac{Z(Z-1)}{A^{1 / 3}}-a_{\text {asym }} \frac{\left(Z-\frac{A}{2}\right)^{2}}{A} \pm a_{\text {pair }} i \sqrt{A}$
- Upon deformation, only the Coulomb and Surface terms will change
- Increased penalty for enlarged surface
- Decreased penalty for Coulomb repulsion because charges move apart
-The volume remains the same because the drop is incompressible

- To change shape, but maintain the same volume, the spheroid's axes can be parameterized as
- $a=R(1+\varepsilon) ; b=\frac{R}{\sqrt{1+\varepsilon}} ;$ where $V=\frac{4}{3} \pi R^{3}=\frac{4}{3} \pi a b^{2}$
- It turns out mand coulomb terms in a power series yields:
- $E_{S}{ }^{\prime}=a_{\text {surf }} A^{2 / 3}\left(1+\frac{2}{5} \varepsilon^{2}+\cdots\right) \quad ; \quad E_{c}{ }^{\prime}=a_{\text {coul }} \frac{Z(Z-1)}{A^{1 / 3}}\left(1-\frac{1}{5} \varepsilon^{2}+\cdots\right)$
- Therefore, the change in energy for deformation is:
- $\Delta E=\left(E_{s}^{\prime}+E_{c}{ }^{\prime}\right)-\left(E_{s}+E_{c}\right)=\frac{\varepsilon^{2}}{5}\left(2 a_{\text {surf }} A^{2 / 3}-a_{\text {coul }} \frac{Z(Z-1)}{A^{1 / 3}}\right)$ ( $\Delta E<0$ is an energetically favorable change)
- Written more simply, $\Delta E(Z, A)=-\alpha(Z, A) \varepsilon^{2}$

To get $\Delta E<0$, need $Z>116, A>270$ !
So we do not expect deformation from this effect alone.
Nonetheless, heavier nuclei are going to be more susceptible to deformation.

## Rainwater's case for deformation

- So far we've only considered the deformation of the core
- However, we also need to consider any valence nucleons
- A non-spherical shape breaks the degeneracy in $m$ for a given $l$, where the level-splitting is linear in the deformation $\varepsilon$.
- The strength of the splitting is found by solving the Schrödinger equation for single-particle levels in a spheroidal (rather than spherical) well and comparing the spheroidal eigenvalue to the spherical one.

Fig. 1. Energy levels for $n=1$. Levels are labeled with the quantum numbers $l, m$ of the undistorted nucleus.

- The total energy change for deformation then becomes: $\Delta E(Z, A)=-\alpha(Z, A) \varepsilon^{2}-\beta \varepsilon$
- The core deformation favors a given $m$, reinforcing the overall deformation
- i.e. the valence nucleon interacts with the core somewhat like the moon with the earth, inducing "tides"
- Taking the derivative with respect to $\varepsilon$, we find there is a favored deformation: $\varepsilon_{\min }=\frac{-\beta}{2 \alpha}$
- Since valence nucleons are necessary to amplify the effect, this predicts ground-state deformation occurring in between closed shells
- Note that the value for $\beta$ is going to depend on the specific nuclear structure, which shell-model calculations are often used to estimate

## Predicted regions of deformation

$$
\beta_{2} \equiv \alpha_{2,0}=\frac{4}{3} \sqrt{\frac{\pi}{5}} \frac{(a-b)}{R_{s p h}}
$$

Measured regions of deformation

## Rotation: Rigid rotor

- The energy associated with a rotating object is: $E_{r o t}=\frac{1}{2} I \omega^{2}$
- We're working with quantum stuff, so we need angular momentum instead where $J=I \omega$
- So, $E_{\text {rot }}=\frac{1}{2} \frac{J^{2}}{I}$
- ...and $J$ is quantized, so $E_{\text {rot }}=\frac{\hbar^{2} j(j+1)}{2 I}$
- Thus our rotating nucleus will have excited states spaced as $j(j+1)$ corresponding to rotation
- For a solid constant-density ellipsoid, $I_{\text {rigid }}=\frac{2}{5} M R^{2}\left(1+0.31 \beta+0.44 \beta^{2}+\cdots\right)$
where $\beta=\frac{4}{3} \sqrt{\frac{\pi}{5}} \frac{(a-b)}{R_{s p h}} \quad$ (A.Bohr \& B.Mottelson, Dan. Matematisk-fysiske Meddelelser (1955))

## Rotation: Irrotational Motion

- Rather than the whole nucleus rotating, a tide-like effect could produce something like rotation
- Here nucleons just move in and out in a synchronized fashion, kind of like people doing "the wave" in a stadium
- Since nucleons aren't orbiting, but are just bobbing in and out, this type of motion is called "irrotational"
- Thankfully, Lord Rayleigh worked-out the moment of inertia for continuous, classical fluid with a sharp surface

(a)

(c)

(b)

[^0](also in D.J. Rowe, Nuclear Collective Motion (1970))

- $I_{i r r o}=\frac{9}{8} \pi M R^{2} \beta^{2}$

## Moment of inertia comparison

- As an example, we can calculate the moment of inertia for ${ }^{238} \mathrm{Pu}$.
- The NNDC chart says for this nucleus $\beta=0.285$
- $I_{\text {rigid }}=\frac{2}{5} M R^{2}\left(1+0.31 \beta+0.44 \beta^{2}+\cdots\right) \approx \frac{2}{5} A\left(r_{0} A^{1 / 3}\right)^{2}\left(1+0.31 \beta+0.44 \beta^{2}\right)$

$$
=\frac{2}{5}(1.2 \mathrm{fm})^{2}\left(A^{5 / 3} \mathrm{amu}\right)\left(1+0.31 \beta+0.44 \beta^{2}\right)=5874 \mathrm{amu} \mathrm{fm}^{2}
$$

- $I_{\text {irro }}=\frac{9}{8} \pi M R^{2} \beta^{2} \approx \frac{9}{8} \pi A\left(r_{0} A^{1 / 3}\right)^{2} \beta^{2}$

$$
=\frac{9}{8} \pi(1.2 \mathrm{fm})^{2}\left(A^{5 / 3} a \mathrm{mu}\right) \beta^{2}=3778 \text { amu } \mathrm{fm}^{2}
$$

- We can obtain an empirical rotation constant for ${ }^{238} \mathrm{Pu}$
- The energy associated with excitation from the $1^{\text {st }} 2^{+}$excited state to the $1^{\text {st }} 4^{+}$state is:
$\Delta E=E_{r o t}^{4+}-E_{r o t}^{2+}=\frac{\hbar^{2}}{2 I}(4(4+1))-\frac{\hbar^{2}}{2 I}(2(2+1))=7 \frac{\hbar^{2}}{I}$
- From NNDC, $E\left(2_{1}^{+}\right)=44 \mathrm{keV} \& E\left(4_{1}^{+}\right)=146 \mathrm{keV}$, so $I_{\text {expt }}=\frac{7}{102} \hbar^{2} \mathrm{keV}^{-1}$
- Take advantage of fact that $\hbar c \approx 197 \mathrm{MeV} \mathrm{fm}$ and $1 \mathrm{amu} \approx 931.5 \mathrm{MeV} / \mathrm{c}^{2}$,

$$
\begin{aligned}
& I_{\text {expt }}=\frac{14}{0.102 \mathrm{MeV}^{2}} \hbar^{2} \frac{1 \mathrm{amu}}{931.5 \mathrm{MeV} / \mathrm{c}^{2}}=0.074 \frac{\hbar^{2} \mathrm{c}^{2}}{\mathrm{MeV}^{2}} \mathrm{amu}=0.074 \frac{(197 \mathrm{MeV} \mathrm{fm})^{2}}{\mathrm{MeV}^{2}} \mathrm{amu} \\
& =2859 \mathrm{amu} \mathrm{fm}^{2} \quad . . c l o s e r ~ t o ~ i r r o t a t i o n a l ~
\end{aligned}
$$

## Empirical moment of inertia

- $E_{r o t}=\frac{\hbar^{2} j(j+1)}{2 I}$, so measuring $\Delta E$ between levels should give us $I$
- It turns out, generally: $I_{\text {irro }}<I_{\text {expt }}<I_{\text {rigid }}$

Fig. 2. Dependence of Nuclear Moments of Inertia on the Nuclear Deformation. The empirical moments of inertia for even-even nuclei in the region $150<$ $A<188$ are plotted as a function of the nuclear deformation. The moments of inertia, obtained from the data in Table I, are given in units of the rigid moment (18), while the deformation parameters $\beta$ are obtained from the $Q_{0}$-values in Table I by means of (19). The nuclear radius has been taken to be $R_{0}=1.2 \mathrm{~A}^{1 / \mathrm{a}}$ $10^{-10} \mathrm{~cm}$. The full-drawn curve represents a theoretical estimate, based on the parison, the moment of inetio correppong to imotion flow is by the dotted curve.
A.Bohr \& B.Mottelson, Dan. Matematisk-fysiske Meddelelser (1955))

## Rotational bands: sequences of excited states

- $E_{r o t}=\frac{\hbar^{2} j(j+1)}{2 I}$, so for a given $I, \Delta E \propto j(j+1)$
- Note that parity needs to be maintained because rotation is symmetric upon reflection and so $0^{+}$ground-states can only have $\mathrm{j}=0,2,4, \ldots$ (because $\pi=(-1)^{J}$ )
- Without observing the decay scheme, picking-out associated rotational states could be pretty difficult

- Experimentally, coincidence measurements allow schemes to be mapped

## Rotational bands

- Rotation can exist on top of other excitations
- As such, a nucleus can have several different rotational bands and the moment of inertia $I$ is often different for different bands
- The different $I$ lead to different energy spacings for the different bands

Figure 1: Partial decay scheme of ${ }^{158}$ Er showing the ground-state, $S$ and $0_{2}^{+}$bands, which are labelled 1,2 and 3, respectively.

[^1]
## Rotational bands: Backbend

- The different I for different rotational bands creates the so-called "backbend"
- This is when we follow the lowest-energy state for a given spin-parity (the "yrast" state) belonging to a given rotational band and plot the moment of inertia and

 square of the rotational frequency

## Inferring structure from rotational bands

- Since $E_{r o t}=\frac{\hbar^{2} j(j+1)}{2 I}$ and $I \propto \beta$, we can use rotational bands to probe deformation
- More deformed nuclei have larger $\beta$, so excited state energies for the band should be low
- The $1^{\text {st }} 2+$ excited state energy is often used to probe this
- The rotor model for rotational bands is validated by the comparison of band excited state energy ratios to the rotor prediction
- The ratio of the yrast $4^{+}$and $2^{+}$excited state energies is generally close to the rotor prediction for nuclei far from closed shells

## Inferring structure from rotational bands

- To keep life interesting, I can change for a single band, indicating a change in structure, e.g. how particular nucleons or groups of nucleons are interacting

## Vibrational modes

- Considering the nucleus as a liquid drop, the nuclear volume should be able to vibrate
- Several multipoles are possible
- Monopole: in \& out motion $(\lambda=0)$
-a.k.a the breathing mode

> The gifs to the right are for giant resonances,
> when all protons/neutrons act collectively

- Dipole: sloshing back \& forth $(\lambda=1)$
- If all nucleons are moving together, this is just CM motion
- Quadrupole: alternately compressing \& stretching $(\lambda=2)$

Isoscalar

- Octupole: alternately pinching on one end $\&$ then the other $(\lambda=3)$ - + Higher
- Protons and neutrons can oscillate separately ("isovector" vibrations)
- All nucleons need not move together
- e.g. the "pygmy dipole" is the neutron skin oscillation

## Vibrational modes

- Additionally, oscillations can be grouped by spin ...leaving a pretty dizzying range of possibilities

Scattering experiments are key to identifying the vibrational properties of particular excited states because one obtains characteristic diffraction patterns.

## Rough energetics of vibrational excitations

- In essence, a nuclear vibration is like a harmonic oscillator
- There is some oscillating deviation from a default shape and a restoring force attempts to return the situation to the default shape
- The restoring force differs for each mode and so therefore do the characteristic frequencies $\omega$, which have a corresponding energy $\hbar \omega$
- Nuclear matter is nearly incompressible, so the monopole oscillation takes a good bit of energy to excite.

For even-even nuclei, the monopole oscillation creates a $0^{+}$state at $\approx 80 A^{-1 / 3} \mathrm{MeV}$

- Neutrons and protons are relatively strongly bound together, so exciting an isovector dipole also takes a good bit of energy
For even-even nuclei, the dipole oscillation creates a 1- state at $\approx 77 A^{-1 / 3} \mathrm{MeV}$
- The squishiness of the liquid drop is more amenable to quadrupole excitations, so these are the lowest-energy excitations
For even-even nuclei, the quadrupole oscillation creates a $2^{+}$state at ${ }^{\sim} 1-2 \mathrm{MeV}$.
The giant quadrupole oscillation is at $\approx 63 A^{-1 / 3} \mathrm{MeV}$
- Similarly, octupolar shapes can also be accommodated

For even-even nuclei, the octupole oscillation creates a 3^ state at $\sim 4 \mathrm{MeV}$

## Vibrational energy levels

- Just as the quantum harmonic oscillator eigenvalues
 are quantized, so too will the energy levels for different quanta (phonons) of a vibrational mode.
- Similarly, the energy levels have an even spacing,

$$
E_{n}=\left(n+\frac{1}{2}\right) \hbar \omega
$$

- Even-even nuclides have 0+ ground states, and thus, for a $\lambda=2$ vibration, $n=2$ excitations will maintain the symmetry of the wave-function (i.e. $n=1$ excitations would violate parity)
- Therefore, the $1^{\text {st }}$ vibrational state will be $2^{+}$
- We can excite an independent quadrupole vibration by adding a second phonon
- The second phonon will build excitations on the first, coupling to either $0^{+}, 2^{+}$, or $4^{+}$
- Employing a nuclear potential instead winds up breaking the degeneracy for states associated with a given number of phonons

## Vibrational energy levels are pretty obvious for spherical nuclei

| $E(\mathrm{MeV})$ $J \pi$ <br> 4.038 $3-\quad$ Octupole vibration |  |
| :---: | :---: |
|  |  |
| Many more levels here |  |
|  |  |
| $1.332 \longrightarrow 2+$ One phonon |  |
| ${ }^{60} \mathrm{Ni} \mathrm{O}+\text { Spherical ground state }$ |  |

G. Harvey, Introduction to Nuclear Physics and Chemistry (1962)
$J^{\pi} \quad E_{\text {ex }}(\mathrm{MeV})$

Matin, Church, \& Mitchell Phys. Rev. (1966)

- The typical signature for vibrating spherical nucleus is $E\left(4_{1}^{+}\right) / E\left(2_{1}^{+}\right) \approx 2$
...though that obviously won't be the case for a deformed nucleus

## Yo dew:g I heard you like collective excitations

D. Inglis, Phys. Rev. (1955)
so 1 put some rotations on your vibrations so you can oscillate while you rotate

## Rotational bands can build on vibrational states

- Deformed nuclei can simultaneously vibrate and rotate
- The coupling depends on whether the vibration maintains axial symmetry or not
- The two types, $\beta$ and $\gamma$, are in reference to how the vibration deforms the shape in terms of Hill-Wheeler coordinates (Hill \& Wheeler, Phys. Rev. (1953))

Side view Top view

$\gamma$-vibration

- Exemplary spectra:

Bohr \& Mottelson, Nuclear Structure Volume II (1969)
$\qquad$

N. Blasi et al. Phys.Rev.C (2014)

## Single-particle states can build on vibrational states

- For some odd-A nuclei, excited states appear to result from the unpaired nucleon to a vibrational phonon
- For ${ }^{63} \mathrm{Cu}$, the ground state has an unpaired $\mathrm{p}_{3 / 2}$ nucleon
- Coupling this to a $2^{+}$state allows $\left|2-\frac{3}{2}\right| \leq j \leq\left|2+\frac{3}{2}\right|$,
i.e. $\frac{1}{2}^{-}, \frac{3}{2}, \frac{5^{-}}{2}, \frac{7}{2}$
- Another example:

$$
\begin{gathered}
\text { Porticle-Core Coupling } \\
{ }^{48} \mathrm{Ca}+2 \mathrm{p}_{3 / 2} \text { or } \quad \mathrm{If}_{7 / 2} \text { neutron }
\end{gathered}
$$

$\left\lvert\, \begin{array}{r}\text { Particle-Core Coupling } \\ { }^{50} \mathrm{Ca}+1 \mathrm{If}_{7 / 2}{ }^{-1} \text { neutron }\end{array}\right.$

B. Harvey, Introduction to Nuclear Physics and Chemistry (1962)

## Recap of basic structure models discussed thus far

- Schematic shell model
- Great job for ground-state $J^{\pi}$
- Decent job of low-lying excited states for spherical nuclei, particularly near closed shells
- Miss collective behavior that arises away from shell closures
- Collective model
- Rotational excitations explain several $J^{\pi}$ for deformed, even-even nuclei These are "mid shell" nuclei, because they're not near a shell closure
- Vibrational excitations explain several $J^{\pi}$ for spherical, even-even nuclei These are "near shell"" nuclei, because they're near a shell closure
- Miss single-particle behavior that can couple to collective excitations

What do we do for collective behavior for odd-A nuclei? the Nilsson model (a.k.a. deformed shell model)

## Nilsson Model: combining collective \& single-particle approaches

- Our schematic shell model was working perfectly fine until you threw it away like a cheap suit because of a little deformation!
Luckily, Mottelson \& Nilsson (Phys. Rev. 1955) weren't so hasty.
- Consider a deformed nucleus with axial symmetry that has a single unpaired nucleon orbiting the nucleus
- We're sticking to axial symmetry because - Most deformed nuclei have this property (mostly prolate)
-The math, diagrams, and arguments are easier
- The nucleon has some spin, $j$, which has a projection onto the axis of symmetry, $K$
- $j$ has $\frac{2 j+1}{2}$ possible projections $K$

- Therefore, each single particle state from our shell model now splits into multiple states, identified by their $K$, each of which can contain two particles (spin up and spin down) for that given projection

## Nilsson model: single-particle level splitting

- Consider the options for our nucleon's orbit around the nucleus
- Orbits with the same principle quantum number will have the same radius
- Notice that the orbit with the smaller projection of $j\left(K_{1}\right)$
 sticks closer to the bulk of the nucleus during its orbit
- Since the nuclear force is attractive, the $K_{1}$ orbit will be more bound (i.e. lower energy) than the $K_{2}$ orbit
- The opposite would be true if the nucleus in our picture was oblate, squishing out toward the $K_{2}$ orbit
- Therefore, for prolate nuclei, lower $K$ single-particle levels will be more bound (lower-energy), whereas larger $K$ states will be more bound for oblate nuclei

## Nilsson model: single-particle level splitting

- Continuing with our schematic picture, we see that the proximity of the orbiting nucleon to the nucleus isn't linear with $K$, $\operatorname{since} \sin \theta \sim \frac{K}{j}$

| $K$ | 1/2 |  | $3 / 2$ |  | $5 / 2$ |  | $7 / 2$ |  | 9/2 |  | 11/2 |  | 13/2 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\theta(\mathrm{deg})$ | 4.4 |  | 13.3 |  | 22.6 |  | 32.6 |  | 43.8 |  | 57.8 |  | 90 |
| $\Delta \theta(\mathrm{deg})$ |  | 8.9 |  | 9.3 |  | 10.0 |  | 11.2 |  | 14.0 |  | 32.2 |  |

R.Casten, Nuclear Structure from a Simple Perspective (1990)

- So the difference in binding for $\Delta K=1$ increases as $K$ increases
- Now, considering the fact that single particle levels of different $j$ can have the same projection $K$, we arrive at a situation that is essentially the two-state mixing of degenerate perturbation theory, where it turns out the perturbation breaks the degeneracy and causes the states to repel each other
 in a quadratic fashion where the strength of the deflection depends on the proximity of the states in energy

Nilsson Model: single particle levels vs $\beta$

Protons: 50<Z<82

Neutrons: 82<Z<126

Protons: Z>82

Neutrons: $\mathrm{N}>126$

## Nilsson Model: Example

- Consider ${ }^{25} \mathrm{Al}$, for which we expect $\beta_{2} \approx 0.2$, like ${ }^{27} \mathrm{Al}$
- There are 13 protons and 12 neutrons, so the unpaired proton will be responsible for $J^{\pi}$
- Filling the single-particle levels,
- We place two protons in the $1 s_{1 / 2}$ level, which isn't shown
- Then two more in $1 / 2^{-}$, two more in $3 / 2^{-}$, two more in $1 / 2^{-}$, two more in the $1 / 2^{+}$, two more in the $3 / 2^{+}$
- And the last one winds up in the $5 / 2^{+}$level
- So, we predict $J_{g . s}^{\pi}=5 / 2^{+}$
- For the first excited sate, it seems likely the proton will hop up to the nearby $1 / 2^{+}$level
- Agrees with data
- Since ${ }^{25} \mathrm{Al}$ is deformed, we should see rotational bands with states that have (integer) $+j$ and $\propto j(j+1)$ spacing
